Name: Braden Shiew Hao Wen

Monash ID: 33273375

Group: Applied_01_MA_G5

1. Brief Overview

Our group worked on the finishing touches of the Software Project CodeVenture. This included cleaning up bugs, implementing missing features, and changing things according to what was observed in the Quality Assurance and Cross-group Evaluation.

2. Individual Breakdown

Tasks and Responsibilities:

> No roles or specific tasks and responsibilities as the work was split evenly and every task was worked on by each member.

Outcomes:

> All members met their goals without much challenge, and everyone helped each other whenever there were issues.

3. Collaboration and Team Dynamics

Group meetings: Group meetings were mostly held online via chat. The group was voiced opinions and split workload efficiently. It is the same as it was in the previous assignments.

Tools used for collaboration/communication: For communication, we used our group on Discord. As for collaborating on the project, we worked on a GitHub Repository.

4. Self-Assessment

Working on the finishing touches, I often find myself struggling to come up with the implementation of the features. After taking my time to research solutions online as well as receiving help from my teammates, I managed to handle it. I realized that I tend to lack the drive and motivation to complete work when I get stuck for too long. I intend to rectify this and not give up so easily.

5. Peer Feedback

I have no complaints whatsoever as everyone greatly contributed to the project, completing their tasks without much trouble. There were no issues with communication either and every point got across clearly just as it was in the previous assignments.

6. Reflection on Unit Learning

Learning Outcomes

1. Describe the capabilities and limitations of software engineering methodologies and approaches, including topical issues for software engineering.
    - Our project utilizes the Waterfall methodology. Work is done in stages, and these stages each have their own requirements and rely on inputs from the previous stages. While this allows development to flow nicely from one stage to the next which minimizes the chance of overlapping work between two stages, it also makes it difficult to make changes later down the road meaning that a clear idea must be had from the beginning.

2. Design and construct responsive web applications using a software engineering methodology and modern web frameworks.
    - The Waterfall methodology was used throughout the unit and each assignment is a step of this methodology. These steps are requirement, design, prototype, quality assurance and the final product.

3. Manage the development process using appropriate IT Tools such as a code editor, debugger, task tracking and team communication tools.
    - Certain tools such as PyTest and using 'assert' can be used to check if a function is outputting expected values.

4. Generate meaningful written technical documentation in a standard format.
    - Source codes should contain meaningful comments detailing the purpose of functions and how they work.

Most positive thing of the unit

The most positive thing about this unit is that we were given a chance to experience the entire process of coming up with a software. From pitching the requirements and design, working on meeting those requirements as a team, and eventually presenting it.

Re-do the unit

If I had to re-do this unit, it would be to thoroughly understand the expectations of the unit before tackling the assignments. A few examples would be that I found it hard to meet the expectations we set in the requirement and design documents as I did not realise how important it was to have a clear idea of what the final product would be during those stages. Another example would be the implementation of a graphical user interface in the final

project. My team initially worked on a terminal-based product but only towards the end did we find out that one of the expectations of the unit is to implement GUI for the project.
